

Worked for 11s

Yes. For PSX/ Pakistan stocks, your current table is **not fully “all-in”** yet. The brokerage commission you show is only one part of the transaction cost.

I checked the current PSX/NCCPL material because the tax/fee structure matters here. PSX explicitly says investors should account for brokerage commission plus regulatory levies and statutory taxes; the exact brokerage and some taxes depend on the broker/jurisdiction. 🌱 P... +1

1. Your SNGP position — first, the important correction

From the **31 actual trade rows** you supplied:

- Shares: **33**
- Actual gross purchase value: **Rs 3,380.53**
- Buy commission: **Rs 6.74**
- Actual purchase cash outflow: **Rs 3,387.27**
- Current price: **Rs 102.50**
- Current market value: **Rs 3,382.50**
- Sell commission: approximately **Rs 6.77**
- P/L before other taxes/levies: **-Rs 11.54**

So your bottom row:

33 shares | Avg Price 3176.27 | Buy Net 3387.29 | Break-Even 3182.83

is mathematically inconsistent.

Your actual average **gross purchase price is about Rs 102.44/share**, while your cost including the stated buy commission is about **Rs 102.64/share**.

That matters a lot when you're trading such small quantities.

2. What should actually be included?

For a PSX trade, I would separate the costs into these buckets:

Cost	Buy	Sell	Should your calculator include it?
Share value	✓	✓	Yes
Broker commission	✓	✓	Yes

Cost	Buy	Sell	Should your calculator include it?
Sales tax on broker/service charges	✓	✓	Yes, if not already included in commission
PSX/NCCPL/SECP regulatory/trading levies	✓	✓ /applicable	Yes
CDC/settlement/custody-related charges	Depends	Depends	Yes when applicable
CVT / statutory levy	Depending on applicable transaction/rules	Depending	Yes when applicable
CGT	—	Only when profitable/realized	Yes
Deposit/withdrawal/bank fee	Sometimes	Sometimes	Yes, but separately

PSX's own investor guidance specifically says contract notes should disclose commission, PSX/CDC/NCCPL/SECP regulatory levies and government taxes/duties.  P...

Also, PSX has moved to T+1 settlement, effective February 9, 2026.  NC...

3. The biggest one for you: CGT

Because these SNGP shares were purchased in August 2026, the current NCCPL schedule puts securities acquired **on or after July 1, 2025** at **15% CGT** for both ATL and non-ATL investors in 2026.  NC... +1

But there's an important distinction:

CGT is not 15% of your sale value.

It is applied to the **capital gain**, after the applicable NCCPL computation.

So if you sell a share at a loss:

CGT = Rs 0

If you make Rs 1 profit:

CGT ≈ Rs 0.15

NCCPL also has its own standardized treatment of acquisition/disposal expenses for CGT calculations rather than simply using whatever brokerage figure happens to be on your statement.  NC...

4. What this does to your SNGP trade

This is where your strategy becomes interesting.

You currently have:

33 shares @ ~Rs 102.44 gross average

At Rs 102.50:

Gross market profit:

Rs 3,382.50 – Rs 3,380.53
= +Rs 1.97

But then:

Buy commission ≈ **Rs 6.74**

Sell commission ≈ **Rs 6.77**

Therefore:

Net before additional taxes/levies ≈ -Rs 11.54

And because you're already negative, CGT doesn't make this worse — there is **no CGT on a capital loss**.

So the real lesson is:

You are not actually trading a Rs 102.44 → Rs 102.50 movement for +Rs 0.06/share.

Your transaction costs eat considerably more than that.

5. Your real break-even is much higher

Ignoring the additional broker/regulatory taxes for a moment:

Total acquisition cost:

Rs 3,387.27

You have to recover that **plus the eventual selling commission**.

Required sale proceeds:

Rs 3,387.27 + ~Rs 6.77 = Rs 3,394.04

÷ 33 shares

≈ Rs 102.85/share

So your **true break-even is roughly Rs 102.85**, not Rs 102.5.

And that's **before any additional taxes/levies that aren't already embedded in your commission figures**.

If we include them, your practical break-even becomes somewhat higher.

6. This exposes something important about your trading strategy

Your SNGP example is actually a very good demonstration of the issue you've been concerned about previously.

You are doing something like:

Buy 1 share at 101.50 → sell around 102.50

Looks like:

+Rs 1/share

But with tiny position sizes, the fixed/percentage transaction costs become huge relative to the profit.

For example:

1 share

Buy 101.50

Sell 102.50

Gross profit:

+Rs 1.00

But:

Buy commission $\approx$ Rs 0.20

Sell commission $\approx$ Rs 0.205

Already:

+1.00 - 0.20 - 0.205 = +Rs 0.595

And that's before other applicable charges/taxes.

So a seemingly successful **1% trade** can produce only a fraction of that as actual money.

7. Your 33-share strategy is therefore inefficient

This is the biggest thing I see in your data.

You traded SNGP in extremely small pieces:

1 share

1 share

1 share

1 share

...

2 shares

...

This is creating a lot of transaction events for a tiny capital amount.

You effectively spent around:

Rs 3,387

to control only:

Rs 3,382.50

of current stock value.

That's not inherently bad, but your target movements need to be large enough to overcome the complete round-trip cost.

8. The calculator should NOT simply use "commission"

For your trading application, I would change the model to:

Buy cost

Gross Buy Value

- Broker Commission
- Tax on Commission
- Exchange/PSX Charges
- NCCPL Charges
- SECP Levy
- CDC/settlement charges where applicable
- Other applicable statutory charges

= True Acquisition Cost

Then:

Sell proceeds

Gross Sell Value

- Broker Commission
- Tax on Commission
- Exchange/PSX Charges
- NCCPL Charges
- SECP Levy
- CDC/settlement charges where applicable
- Other applicable charges

= True Sale Proceeds

Then:

Realized P/L

True Sale Proceeds – True Acquisition Cost – CGT

That is the number you actually care about.

9. But don't put CGT into the ordinary break-even incorrectly

This is important.

Suppose:

True cost = Rs 10,000

and you sell for Rs 10,100.

Your profit before CGT = Rs 100.

At 15% CGT:

CGT $\approx$ Rs 15

Final profit:

Rs 85

But if you sell for Rs 9,900:

Loss = Rs 100

CGT:

Rs 0

So your calculator should have two different concepts:

Operational Break-even

Price needed to recover all transaction costs.

and

After-tax profit

Profit after CGT.

That's much cleaner.

10. Your table should therefore become something like this

Column	Meaning
Gross Buy	Shares × Buy Price
Broker Buy Commission	Your current commission
Buy Tax	Tax on commission
Buy Regulatory Fees	PSX/NCCPL/SECP etc.
Buy Other Fees	CDC/etc.
True Buy Cost	Everything paid
Current Price	Market price
Current Gross Worth	Shares × Current Price
Gross P/L	Worth – gross purchase
Estimated Sell Commission	Current rate
Estimated Sell Taxes	Tax on commission
Estimated Sell Regulatory Fees	PSX/NCCPL/SECP etc.
Net Sale Proceeds	After all selling costs
Pre-CGT P/L	Net sale – true buy cost
CGT	Only if positive taxable gain
Final P/L	After CGT
True Break-even	Price required for final P/L = 0

That would be **far more honest** than the current **P/L** column.

One caveat: I don't want to invent the missing charges

Your exact **broker name and contract-note tariff** are needed to put precise rupee amounts into every row.

PSX explicitly notes that brokerage commission varies by broker and that the customer tariff should show the applicable commission, regulatory levies and statutory taxes.

So I would **not** hard-code something like "0.15% tax" or "15% sales tax" into your application without checking your broker's actual contract note. Some charges are broker/jurisdiction-specific.

What I would do in your trading app

Have a **Fee & Tax Engine** with:

- Brokerage %
- Brokerage minimum
- Sales tax on brokerage
- PSX transaction fee
- NCCPL fee
- SECP levy
- CDC charges
- CVT
- CGT
- Deposit fee
- Withdrawal fee
- Other broker-specific charges

and a switch for:

"Already included in broker commission?"

That prevents double-counting.

Your current SNGP data strongly suggests that this is necessary: **the apparent small profits from 1–2 share trades are being substantially consumed by round-trip costs.**

And this also strengthens your earlier concern about averaging down: **adding more shares can reduce the average price mathematically, but it does not magically recover the money already lost—and every additional buy creates another layer of transaction cost.**
